Institute for Information Security, Moscow State University

On Testing Network Quality Of Service – p. 1

The Test Network Structure

PC1–PC2 is the bottleneck link: VBR-RT circuit to model physical link

On Testing Network Quality Of Service – p. 3

The Purpose Of The Test Network

- ⑥ Testing of modern QoS mechanisms
- ⑥ How they fit into MPLS infrastructure
- ⑥ Whether math. models adequately describe them

On Testing Network Quality Of Service – p. 2

The Test Network Structure

Description of components:

- ⑥ PE1, PC1 — Moscow State University
- ⑥ PE2, PC2 — Russian Institute for Public Networks
- ⑥ PC1–PC2 — virtual ATM circuit via MSK-IX
- ⑥ T1, T2 — computers running Linux

2 networks:

- ⑥ Test MPLS network
- ⑥ Control network (common Internet)

On Testing Network Quality Of Service – p. 3

Software Used

Software created for the project:

- ⑥ UDP traffic generator, collector and packet logger.
- ⑥ Statistical analyzer of collected logs.

Other software used:

- ⑥ Iperf — for generating background TCP traffic.
(<http://dast.nlanr.net/Projects/Iperf/>)

On Testing Network Quality Of Service – p. 4

UDP traffic generator

Components:

- ⑥ `cbr_test` — generator
- ⑥ `cbr_sink` — collector
- ⑥ `unilog.pl` — packet log producer

Order of an experiment:

1. Run `cbr_sink` on T2.
2. Run `cbr_test` on T1 and wait for it to finish.
3. Move data logs onto one PC.
4. Use `unilog.pl` to make packet log.
5. Use a statistical analyzer.

On Testing Network Quality Of Service – p. 5

UDP traffic generator

Features:

- ⑥ Constant rate, constant packet size (for now).
- ⑥ Collector may answer received packets to measure RTT precisely.
- ⑥ Precise timer for sending packets.
- ⑥ Control on IP addresses and UDP ports used.
- ⑥ Every sent or received packet logged.
- ⑥ Command line interface.

Written in C and perl to be used on Linux.

On Testing Network Quality Of Service – p. 5

StatQoS — Statistical analyzer

- ⑥ Takes packet log from `unilog.pl`.
- ⑥ Makes a report, calculates QoS parameters observed.

Features:

- ⑥ Processes large logs effectively, as an whole or by parts.
- ⑥ Calculates packet losses in each direction (T1 → T2, and T2 → T1).
- ⑥ Analyzes RTT and jitter: minimum, maximum, average, dispersion, histogram.
- ⑥ Dialog interface.

On Testing Network Quality Of Service – p. 6

Tests Performed

- ⑥ Calibration: checking a stability of the virtual ATM circuit, how well it can represent a dedicated physical link.
- ⑥ Priority queueing.
- ⑥ Fair queueing.

On Testing Network Quality Of Service – p. 7

Calibration

- ⑥ Continuous testing during 2 weeks.
- ⑥ 400 packets/sec with 1200 bytes of payload each.
- ⑥ Collector replied on every received packet.

Analysis of the results made possible to separate effects of QoS mechanisms, tested later, from «background noise».

On Testing Network Quality Of Service – p. 8

Calibration results

- ⑥ Average RTT was 11–12 milliseconds.
- ⑥ Packet loss was less than 10^{-8} .
- ⑥ There was easily detectable and measurable (with our software tools) influence by uncontrolled external factors.

Conclusion: virtual ATM circuit had measurable differences from real dedicated link, but was good enough for our tests.

On Testing Network Quality Of Service – p. 9

Testing Priority Queueing

CBWFQ (Class-Based Fair Queueing) was used on Cisco routers to test priority queueing and fair queueing.

Test scenario:

- ⑥ Low-rate UDP flow for priority class.
- ⑥ Several TCP flows, generated by `Iperf`, for best-effort class. 6 and 25 flows in our tests.

Fair Queueing testing: UDP flow was put in same best-effort class.

On Testing Network Quality Of Service – p. 10

Test Results

Observed were good QoS parameters, perfectly suitable for e.g. voice traffic.

- ⑥ Average RTT was 12 milliseconds.
- ⑥ No packet loss during 2 days and more than 3 million packets.
- ⑥ Less than $3 \cdot 10^{-6}$ of all packets had RTT greater than 50 milliseconds.

Test Results

Practical utility of our software tools was observed: non-optimal configuration and errors of configuration were detected on test network during experiments.

Example: no good QoS for priority traffic was obtained before changing `tx-ring-limit` value for the ATM PVC.

On-going experiments and future plans

- ⑥ Class-Based Queueing: static and dynamic case.
- ⑥ Modeling other traffic sources: bursty, interactive, etc.
- ⑥ Developing and testing full QoS-enabled network infrastructure: dynamically changing, applying and enforcing policies.
- ⑥ Developing and modeling new QoS mechanisms.
